

YAG Laser Treatment

For Posterior Capsule Opacification (PCO)

What is PCO?

After cataract surgery, some people develop a cloudy membrane behind the new lens implant. This is called posterior capsule opacification (PCO). It is not dangerous, but it can make your vision blurry again, similar to before your surgery.

What is a YAG laser treatment?

YAG laser capsulotomy is a quick and painless laser procedure that clears the cloudy capsule behind your lens. It restores clear vision by making a small opening in the capsule to let light through again.

Why is it done?

You may need this if you:

- Had cataract surgery and your vision has become cloudy again
- Have trouble seeing clearly, reading, or driving due to glare or blur
- Want to improve your vision without needing more surgery or eye drops

How does it work?

- The YAG laser creates a tiny opening in the back of the lens capsule
- This lets light pass through clearly again
- The procedure takes only a few minutes

What happens during the procedure?

- Done in the clinic while you are awake
- Your eye will be dilated with drops
- You may feel mild pressure or see flashes of light, but it is not painful
- You can usually go home right after
- Your vision may be blurry for a few hours afterward

What should I expect after?

- Vision usually improves within 1 to 2 days
- You may see floaters for a few days
- Most people return to normal activities the same day
- Your doctor may check your eye pressure later that day or the next day

Is it safe?

YAG laser treatment is safe and very commonly done. Serious complications are rare.

Possible side effects

- Mild discomfort or inflammation
- Floaters
- Temporary increase in eye pressure
- Very rarely: swelling, retinal detachment, or lens implant damage

When to call your eye doctor

Contact your clinic if you notice:

- Eye pain that gets worse
- A large increase in floaters or flashing lights
- Sudden loss of vision
